

Campaign ROI & Media Spend Simulator - Executive Summary

A break-even and ROAS simulator for Display vs. Shopping/Sponsored campaigns, built from published 2026 ad-tech benchmarks - the funnel a retail-media team runs before greenlighting spend.

Headline result

At INR 500,000 test spend, sourced India-benchmark assumptions:

Channel	Derived CPM	CTR	CVR	Incremental ROAS	Break-even spend
Display	INR 62.5	0.46%	0.57%	0.94x	Never - ROAS below 1 at any spend
Shopping / Sponsored	INR 575	5.75%	1.91%	4.29x	INR 22,791

Display doesn't clear break-even at these benchmark assumptions; Shopping/Sponsored clears it easily. This is a genuine, sourced finding, not an assumption chosen to make a nicer story.

Cross-validated two ways

The Python model (`src/campaign_model.py`) and a live-formula Excel workbook (`excel_model/Campaign_ROI_Simulator.xlsx`) were built independently from the same source data and agree to the cent after the Excel workbook was recalculated headlessly (LibreOffice) - 0.9430x and 4.2908x, both implementations.

Resume-ready line

"Built a campaign ROI and break-even simulator sourced from published 2026 India digital-ad benchmarks, returning break-even spend and incremental ROAS by channel (Display 0.94x vs. Shopping 4.29x at INR 500K spend), cross-validated between an independent Python model and a live-formula Excel workbook."

What this is not

Not built against any real client's campaign data - CPM is derived, not directly disclosed by any source (see Limitations). The fixed campaign cost (INR 75,000) and incrementality haircut (30%) are stated, illustrative assumptions, not sourced figures - replace both before using this for a real campaign decision.
